# **Pay as you use in Golem**

MARCIN BENKE, R&D ADVISOR

# What is Golem

01 \_\_\_\_\_

A network of computing resources that can either be used by a requestor or provided to other participants by a provider.

02 \_\_\_\_\_

A decentralised marketplace based on Ethereum tokens

golem  
NETWORK

**golem**  
NETWORK

## REQUESTOR

of computing power  
*demand side of the market*

**golem**  
NETWORK

## REQUESTOR

of computing power  
*demand side of the market*

## PROVIDER

of computing power  
*supply side of the market*

**golem**  
NETWORK

# Pricing work

## Fixed Price

safe for requestors, big  
risk for workers when  
job size unknown

## Time & Materials

safe for workers,  
overcharge risk for  
requestors, especially for  
remote work

**PRICING WORK**

# Time & Materials

01 \_\_\_\_\_

Is FP really better for buyers than T&M?

02 \_\_\_\_\_

Fair to both sides if they are honest

03 \_\_\_\_\_

How to bid on tasks with unknown size?

04 \_\_\_\_\_

Workers need to include risk premium in their price.

# Time & Materials

01 \_\_\_\_\_

Generally good choice  
if job size unknown

02 \_\_\_\_\_

Fair to both sides if  
they are honest

03 \_\_\_\_\_

Risk of overcharge by  
dishonest workers

04 \_\_\_\_\_

Requestor still has the  
option not to pay at all

# Pay as You Use

## Existing model

- So far Golem used FP contracts
- General computations are hard to estimate

## Pay as You Use

- A new T&M billing model for Golem
- Providers charge for resource usage (e.g. CPU time)
- Enables new use cases e.g. WASM computing

# The main challenge of T&M

RECEIPT

\_\_\_\_\_

- What if a provider inflates resource usage?
- Budget limit provides partial protection
- Ensure sustainability of the economy in the long term
- Eliminate cheaters from the market
- Focus on long-term cost rather than single transactions
- How to detect & prevent fraud?

# Fraud detection & prevention

- Quest for information: what is the job worth?
- A priori information sources:
  - human input
  - algorithmic estimation
- A posteriori - comparisons
  - punishing worst workers
  - comparable tasks (task farming)
  - cross-checking (redundancy)

# Comparing and choosing offers

Providers offer prices per resource unit. To compare offers, requestors rate provider efficiency

Usage factor

$R$  = resources needed to compute a reference task.

Offers compared according to  
 $R * \text{price}$

# Comparable tasks

- Multiple jobs with the same complexity
- Great source of information
- Use cases: task farming (e.g. mathematical or molecular modelling)
- Adjust usage factors to the weighted geometric mean

1 task  
2 h  
R = 2

1 task  
30 min  
R = 0.5

1 task  
1 h  
R = 1

# Cross-checking (redundancy)

- The same task executed by 2 or more providers
- Context: result validation by cross-checking (redundancy)
- Honest providers should report similar effective usage
- Otherwise penalize provider with excessive usage

# Simulations

● Number of  
computed tasks

● Revenue

10 honest vs 2 dishonest

10 honest vs 3 dishonest

# Coming Next: Game-theoretic approaches

- 01** Provider submits the price and hash of the results
- 02** Requestor decides if it wants the results for this price
- 03** Requestor still needs to decide whether the price is fair

# Conclusions and future work

01 \_\_\_\_\_

We want Golem to be a good fit for general computation not only technically, but also economically

03 \_\_\_\_\_

We plan to introduce it on mainnet along with WASM use-case

02 \_\_\_\_\_

We propose a simple, yet efficient Pay as You Use solution

04 \_\_\_\_\_

We keep improving our solution

# Thank you

SUBSTANTIAL KNOWLEDGE: Łukasz Gleń, Jakub Konka

DESIGN: Natalia Mroszczyk

**GOLEM.NETWORK**

# Usage Factor adjustment

Providers with nominal usage factors  $R_1, \dots, R_n$  report usages  $u_1 \dots u_n$ . Let

$$R = G(R_1, \dots, R_n)$$

$$u = G(u_1, \dots, u_n)$$

be their geometric averages.

Nominal and actual factors relative to the mean

$$v_i = u_i / u$$

$$\rho_i = R_i / R$$

Should be equal if  $R$  and  $u$  are accurate

# Usage Factor adjustment

We move the R-factors of the providers towards the actual usage

$$R'_i = R_i \left( \frac{v_i}{\rho_i} \right)^q$$

Updated relative usage factors are the weighted geometric mean

$$\rho'_i = R'_i / R = v_i^q \rho_i^{1-q}$$
